TITLE: On the possibility of using NO - H₂O isotope exchange in nitric acid solutions for concentrating ¹⁸O

PERIODICAL: Soobshcheniya akademii nauk Gruzinskoy SSR, v. 29, no. 3, 1962, 289-292

TEXT: The heavy isotope ¹⁵N can be obtained by isotope exchange in the system: nitric acid (aqueous solution) - nitric oxide, the isotope being concentrated in the aqueous phase. The gaseous phase of the same system contains increased quantities of the heavy isotope ¹⁸O. Isotope exchange occurs between NO and H₂O and is accelerated by HNO₃. Exchange columns, used for concentrating ¹⁵N, can also be utilized for increasing the rate of this process. The apparatus for the separation of ¹⁸O and the apparatus for ¹⁵N concentration can be operated simultaneously. The authors con-

structed an apparatus in which NO was decomposed at a temperature above 700°C. The nitrogen peroxide formed was dissolved in H₂O in an absorber and H₂O separated from the NO residue in a contact apparatus at 750 - 800°C (using an Fe catalyst). The experiments were carried out in a 10 mm diameter column (1.5 mm x 1.5 mm Levin spirals as packing, length 1.8 m). The observed oxygen losses (6×10^{-3} g/l) exceeded the calculated permissible values, even on cooling to 0°C. Losses could probably be reduced by sorption of the steam on molecular sieves and subsequent recycling. There are 3 figures.

ABSTRACT: The Experimental Laboratory, Department of Electrical Machines and Instruments, Gor'kiy Polytechnic Institute im. A. A. Zhdanov (issledovatel'skaya laboratoriya kafedry elektricheskikh mashin i apparatov Gor'kovskogo politekhnikeskogo instituta) has manufactured and tested static ferromagnetic frequency converters with ferrite cores (FSPCh). Such converters may find extensive use in automation. The power of individual converters ranges from 30 to 200 w. Electromechanical generators (output voltage frequencies $f_1 = 400, 1000, \text{ and } 2500 \text{ cps}$) were used as power sources. The magnetization winding circuit was

switched into a d-c source through a "closing" circuit $L\phi\phi$. Longitudinal compensation capacitor, C_1 , were switched into the secondary winding circuits. FSRCh for a higher frequency of power were designed according to circuits involving one-stage, cascade, and self-magnetization of the intermediate harmonics of the flow (Fig. 1). The cores of all the converters were made of brand 3000NM Mn-Zn ferrite. Tests showed several features of the

TITLE: Travelling wave tubes as UHF detectors and mixers

PERIODICAL: Radiotekhnika i elektronika, v. 7, no. 5, 1962,
838 - 843

TEXT: The purpose of the paper is to investigate experimentally the detector and mixer properties of ordinary low power travelling wave tubes in the 10 cm and 3 cm range. The input signal (and the local oscillator signal in case of mixing) is fed into the travelling wave tube and the detected signal (or i-f signal) is taken from the collector circuit. The voltages on the different electrodes are the same as in amplifier operation except that of the collector which is considerably depressed. The collector current in the absence of input signal depends very strongly on collector voltage. The collector current in the presence of signal is altered. The current difference, ΔI_k , and its ratio to input power, $\Delta I_k/P_c$, are plotted

Card (1/2)

Travelling wave tubes as UHF ...

S/109/62/007/005/009/021
D266/D307

against input power. For small input power ($P_c < 5\mu W$) the detector characteristics are near to quadratic. The minimum detectable signal was found to be about 10^{-10} watt which is of the same order as that obtainable by a TWT-crystal combination. In mixer operation the chosen i-f frequency was 40 Mc. The dependence of conversion gain and i-f power on input power is plotted, showing about 17 db conversion gain in low level operation. I-f power plotted against local oscillator power shows a maximum around $P_{10} \approx 50 - 70$ microwatts. The limit sensitivity of the travelling wave tube mixer was found to be worse than that of the TWT-crystal by 5 to 10 db. The bandwidth of the mixer was not determined but in each case it exceeded 10 %. Some experiments were also performed by feeding back the higher frequency to the input of the travelling wave tube. The limiting sensitivity improved in this case by approximately 3 db. There are 6 figures.

1952. Organic co-precipitation. III. Co-precipitation of thallium. V. I. Kuznetsov and G. V. Myasoyedova (V. I. Vernadskii Inst. Geochem. and Anal. Chem. Acad. Sci. USSR, Moscow). *Zh. Anal. Khim.*, 1952, 26 (4), 211-216. Thallium in the form $TlCl_3$ at concn. $\times 10^3$ to $0.2 N$ HCl is quantitatively co-precipitated with the ppt. formed by *p*-dimethylaminocobenzene and methyl orange. Antimony in the form $SbCl_3$, $AuCl_3$, Mo and W (particularly as heteropoly acids) and partially Fe^{3+} are also pptd. Thallous ions are not pptd. hence separation of Tl from all other elements is effected by a co-precipitation of the interfering ions with the organic ppt. in the presence of H_2O_2 which remains in solution, treatment of the filtrate with chloride of lime to give $TlCl_3$, and a further co-precipitation to obtain Tl only. The method is applied to the determination of 10^{-4} to 0.1 per cent of Tl in granites and other silicates. G. S. Smith

Author : Kuznetsov, V.I., ~~Myasovedova, G.V.~~
Title : Use of Organic Coprecipitants in Study of Reaction Course in Highly Dilute Solutions.

Orig Pub : Zh. neorgan. khimii, 1956, 1, No 3, 579-585

Abstract : Organic coprecipitants (OC) are chosen for investigation of the reactions of complex-formation (K) or of redox in very dilute solutions, in such a manner that OC is precipitated in conjunction with only one kind of ions of the given element while the other remain in solution. To study the velocity of $KCr(3+)$, tagged with Cr^{51} , with Eriochrome Blue-Black T (I), use was made, as OC, of the precipitate formed on interaction of I with Methyl Violet (II). This precipitate entrains, at pH 4, only the complex of $Cr(3+)$ with I. Hence on adding II after various predetermined time intervals

C.

Abs Jour : Referat Zhur - Khimiya, No 2, 1957, 4123

following incorporation of I into the Cr(3+) -containing solution and determining thereafter the activity of the precipitate an opinion is formed concerning the kinetics of K. Curves of K kinetics in 2.10 and 2.10 M solutions of Cr(3+), at 50°, coincide. At 70° rate of K is considerably higher than at 50°. To study kinetics of the reaction $Tl^+ + 2FeCl_4^- \rightleftharpoons TlCl_4^- + 4Cl^-$ (1) there is used

as OC the precipitate formed on interaction of p-dimethylamino azobenzene with Methyl Orange (III). This OC entrains only $TlCl_4^-$, without precipitating Tl^+ . In a solution wherein the concentrations are: $Tl^+ 2.4 \cdot 10^{-9}M$, HCl 0.2N, $Fe^{3+} = Fe^{2+} 1.10^{-4}M$, the equilibrium (1) becomes established at 20° within ~ 3 hours. The method of OC is suitable for the study of distribution of elements between various complex-forming agents, provided that:
a) the OC entrains only one of the complexes that are

Card 2/3

- 33 -

USSR/Inorganic Chemistry - Complex Compounds

Abs Jour : Referat Zhur - Khimiya, No 2, 1957, 4123

C.

formed, b) the ionic equilibria do not become established too rapidly, and c) these equilibria do not change very much during coprecipitation. As a result of study of the distribution of Zn (tagged with Zn^{65}) between such complex-forming agents as NH_4SCN (IV) and Complexon III (V), it was ascertained that the extent of coprecipitation of Zn changes little with concentration of Zn, but depends greatly upon the concentration ratio of IV:V. As OC was utilized the precipitate that is formed on interaction of II with III. In the opinion of the authors the state of ionic equilibria in the solution does not undergo substantial changes during the coprecipitation.

✓ Possible losses of thallium during the analysis of silicates
 V. I. Kuznetsov and G. V. Myasoyedova (V. I. Vernadskii
 Inst. Geochem. and Anal. Chem., Acad. Sci. U.S.S.R.,
 Moscow). *Zhur. Priklad. Khim.*, 29, 1875-8(1956).—In
 fusions with Na_2CO_3 of mixts. contg. from 0.1 to 1000 μTl
 as much as 97-9% of it is lost (detected with Tl^{++}). The
 addn. of 0.5 g. BaSO_4 , WO_3 , MoO_3 , or Nb_2O_5 did not reduce
 the loss of Tl. In the presence of SiO_2 or CaCO_3 the losses
 of Tl are reduced from 99-100% to 70%. During the treat-
 ment of silicates with HCl in the presence of H_2SO_4 or HCl
 there is no loss of Tl, probably because this is done at low
 temps.

TITLE: Organic Co-Precipitants (Organicheskiye soosaditeli).
Communication 9: The Concentration and Spectrographic Determination of Molybdenum in Natural Waters (Soobshcheniye 9. Kontsentrirvaniye i spektral'noye opredeleniye molibdena v prirodnykh vodakh)

PERIODICAL: Zhurnal analiticheskoy khimii, 1958, Vol. 13, Nr 4, pp. 453-456 (USSR)

ABSTRACT: In natural waters flowing through the area of an ore deposit and containing up to 1-2g/l minerals the content of molybdenum usually does not exceed 10^{-7} - 10^{-6} g/l; in special cases it may rise to 10^{-3} - 10^{-4} g/l (Ref 1). As the content of molybdenum and other trace elements in natural waters is usually below the sensitivity of spectrographic methods, these elements must first be concentrated. This concentration may be realized by the evaporation of water or by the extraction and co-precipitation of inorganic and organic co-precipitation reagents. In the methods described in publications (Refs 2-5) for the quan-

Card 1/4

SOV/75-13-4-14/29

Organic Co-Precipitants. Communication 9: The Concentration and Spectrographic Determination of Molybdenum in Natural Waters

titative determination of molybdenum in natural waters the molybdenum is determined photometrically after the concentration. A method for the spectrographic determination of molybdenum in the dry residue of natural waters (Ref 5) makes possible the determination of $2 \cdot 10^{-4}$ % Mo with an error of ± 10 %. An important disadvantage of this method is the rapid decrease of the sensitivity with an increasing mineral content of the water. At a content of 5-10g/l this method is already hardly suited for this purpose. By the concentration of molybdenum this disadvantage may, however, be removed. The co-precipitation of molybdenum with the tannate of methyl violet (Ref 7) is well suited for the concentration. In 0.2 n hydrochloric acid solution molybdenum is in this way qualitatively co-precipitated, while Ca, Mg, Na, K, and other elements forming the main part of the mineral content of the water are not carried over by this precipitate. The concentration of molybdenum with organic co-precipitants at the same time removes the influence exerted on the spectrographic determination by the mineral content of the natural waters. The authors investigated the suitable

Card 2/4

SOV/75-13-0-10/20

Organic Co-Precipitants. Communication 9: The Concentration and Spectrographic Determination of Molybdenum in Natural Waters

bility of this method of concentration and they designed a working instruction for the concentration of molybdenum in natural waters by means of the tannate of methyl violet and for the subsequent spectral analytical determination of molybdenum. Per 100 ml of a 0,2 n hydrochloric acid solution 5 ml of a 2% solution of methyl violet and 2,5 ml of a 2% tannin solution are added. The precipitate is filtered off and after the addition of 30 mg of a "carrier" consisting of anhydrous Na_2SO_4 , CaSO_4 and MgSO_4 at temperatures not exceeding 500° they are annealed. The molybdenum is spectrographically determined in the residue when using an a. c. carbon arc as excitor of the spectrum, and when measuring the absolute intensity of the most sensitive line of molybdenum (Mo 1R at $3132,6 \text{ \AA}$) this way amounts of from $0,3$ to 27μ of molybdenum may be determined with an error of $\pm 12\%$. This method makes it possible to determine $0,3 \mu$ molybdenum in 1 l water of any mineral content. The spectra are photographed by a quartz spectrograph of the type **ISP** -22, the blackening of the analytical lines of molybdenum and of the

TITLE:

Method of Remote Recording of Essential Physiological Func-
tions in Men by Means of Radiotelemetry

PERIODICAL:

Voyenno-meditsinskiy zhurnal. 1960. No. 2, pp. 70-72

TEXT: The authors describe a method devised by them in 1949 of record-
ing physiological functions in men during flight by means of a radio
telemetric device. According to the authors, this method is still app-
lied. It permits the recording of respiratory frequency, body tempera-
ture, oxygen pressure under the mask, pressure in the stress device of
the pressurized suit, flight altitude, pressure in the cabin, overstrain
etc. The respiratory movements of the chest are transmitted to a feeler
which is fastened to the chest. The scheme of the feeler may be seen in
Fig 1. By means of the feeler the respiratory movements are transformed in
to voltage fluctuations of direct current. The voltage fluctuations of the

B023/B066

feelers are received by a commutator and pass over to a converter which transforms them into sound frequency. This sound frequency is transferred by means of the radio transmitter from the airplane to the earth, transmitted and recorded on photographic paper. The radiotelemetric device can operate with potentiometric and with carbon feeler. Tensiometers may be applied for this purpose as well. Fig. 2 shows the scheme of a simple device for recording physiological functions of the pilot. The authors fitted the transmitter of the radiotelemetric device in the airplane and in adequate position feelers to record the parameters mentioned above. The respiration feeler is applied under the suit with only a low tension in order to prevent a hampering of the pilot's movements. Fig. 3 shows curves of the respiration movements. Also changes of the type of chest movements in dependence on the external pressure are recorded there. Fig. 4 presents curves which illustrate the chest movements in great altitudes and on sudden change of the surrounding atmospheric pressure. The examples given do not completely cover the entire range of applicability of the method discussed. According to the authors, it may be widely and successfully applied in the

AUTHOR: Myazdrikov, O. A.

TITLE: An Integrating Detector of Penetrating Radiation.
Letter to the Editor

PERIODICAL: Atomnaya energiya, 1960, Vol 8, Nr 1, pp 64-65 (USSR)

ABSTRACT: The author investigated the influence of penetrating radiation on the electret state of the dielectric (frozen polarization) trying to develop a law for the change in time of surface charge density. The model used is shown in Fig. 1. A gas volume Z_G under a pressure P_G is over the upper surface of the dielectric Z_D holding the charge density σ . The change in σ during exposure is due to energy absorption in both the volume of the gas V_G and the volume of the dielectric V_D . Swann derived an equation for the field in the gaseous region

Card 1/8

An Integrating Detector of Penetrating
Radiation. Letter to the Editor

77223
SOV/89-8-1-17/29

$$E = \frac{4\pi\sigma Z_0}{\epsilon_D Z_0 + Z_0} \quad (1)$$

where ϵ_D is the dielectric constant. E rises to more than a few hundred volts, and causes a saturation current density j_G of ions produced in the gas. Ions cannot neutralize the bound charges of the electret and their field, and, therefore, they reduce the value of σ . In the dielectric, the efficiency of pseudo-dipole hole-electron pair creations depends partially on the kind of radiation. The effects on the dielectric give rise to a dielectric leakage-current density j_D . Writing I for the intensity of radiation, the

Card 2/8

An Integrating Detector of Penetrating Radiation. Letter to the Editor

1985

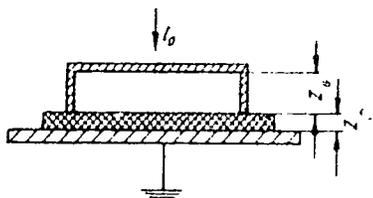

Fig. 1. Model of the detector.

author describes the behavior of the frozen polarization during the radiation process in the form

$$-\frac{d\sigma}{dt} = I_0 + I_0 \left[k_1 \int_{V_0} \text{div } I dV + k_2 \int_{V_1} \text{div } I dV \right] \quad (2)$$

Card 3/8

An Integrating Detector of Penetrating
Radiation. Letter to the Editor

77222
507/89-2-1-17/29

which in the case of full electron equilibrium and saturation in V_G (in the case of γ -rays) goes over into the equation

$$-\frac{d\alpha}{dt} = cZ P_\gamma \frac{P_r}{P_0} \pm \mu_{of} \mu Z l. \quad (3)$$

where c is the electrical equivalent of a Roentgen; P_γ is the strength of the γ -ray dose; μ_D is the linear absorption coefficient of the dielectric (for $h\nu > 1$ mev it is mostly due to Compton scattering); μ_{of} is the moment of the pseudodipole; and P_0 is the atmospheric pressure. The first term in Eq. (3) represents the ion current density in the gas, and the second is due to the pseudodipole creation in the

Card 4/8

Radiation. Letter to the Editor

1977
RGV 86-1-1-1, 2, 3

dielectric. Since nonrelativistic energies are $\epsilon_1 \gg \epsilon_2$, one can neglect the second term in (7), and after integration obtain

$$D = \frac{\Delta\sigma}{\epsilon_1} \frac{P_0}{P}, \quad (7)$$

i.e., variation of the density $\Delta\sigma$ is a measure for the size of the dose D. The results of experimental verifications of Eq. (7) for three values of Z_G is shown in Fig. 2. The electret appears here as an integrating detector for radiations. An electret made from organic materials containing hydrogen can interact with a neutron flux through proton recoils, and the pertinent equation is then

Card 5/8

An Integrating Detector of Penetrating
Radiation. Letter to the Editor

111223
SOV/89-3-1-17/29

$$-\frac{d\sigma}{dt} = FZ_c P_{no} \quad (8)$$

Where P_{no} is the neutron flux density; and F is a function whose numerical values are computed using the percentage content of hydrogen nuclei. The sensitivity of the detectors for γ -ray and neutron fluxes can be adjusted in a wide range according to the Eq. (8) and (9).

$$S_{\gamma} = c / \frac{P_{\gamma}}{P_n} \quad (8)$$

$$S_n = F Z_c \quad (9)$$

no.18, 1962, 10, abstract 18 B 54. (Izv. Leningr.
elektrotekhn. in-ta, no.46, 1961, 289-293).

TEXT: The previously known relationship between the surface charge density of an electret σ and the atmospheric pressure, which is of the shape of a Paschen curve, was checked. The value of σ_{max} depends on the charge of the adsorbed gas ions which are characteristic for any given electret. The life of the adsorbed charge does not exceed a few days. An attempt is made to assess the value of the adsorbed charge and to explain its physical nature.

TITLE: The storage mechanism of electret detectors in integral operation

PERIODICAL: Referativnyy zhurnal, Fizika, no. 10, 1962, 18, abstract 10B:33
("Izv. Leningr. elektrotekhn. in-ta", 1961, no. 45, 294 - 299)

TEXT: A theoretical explanation is suggested for the storage mechanism of electret detectors measuring radiation doses in integral operation. According to the scheme suggested, the storage results from the following processes: a) the process of adsorption, at the electret surface, of ions of the gas having a sign opposite to that of the charge of the electret side; b) the process of the space charge created by ions of the gas in the thin surface layer of the dielectric, and c) the tip-over process of the surface layer dipoles on account of the energy acquired by them during collision with the ions. An experimental study of the storage time error of the electret detector qualitatively confirmed the participation of the first two processes in the storage mechanism. An experimental verification, conducted with multicomponent organic electrets made from

TITLE: High-voltage generator based on the fission reaction

PERIODICAL: Referativnyy zhurnal, Elektrotehnika i energetika, no.1, 1963, 16, abstract 1 A 95. (Izv. Leningr. elektrotekhn. in-ta, no.46, 1961, 340-343)

TEXT: The constructional principles are discussed of a generator in the form of a self-charging system placed in a vacuum and including a fissile layer in which a self-sustaining chain reaction takes place. Such a generator operates as a high-voltage, constant-current generator whose current output is independent of the load resistance and produces a power

$$P = 2 \theta E_0 \sigma_f I_{no} N \Delta x \varphi S$$

where: E_0 is the energy of the fragments; θ is a coefficient describing residual energy losses of a fragment when it strikes the collector; N is the number of nuclei in the fissile material per cm^3 ; φ is a coefficient representing the fission fragments emitted in the direction of the collector;

I_{no} is the neutron-flux density; Δx is the thickness of the fissile layer; S is the area of the layer and σ_f is the fission cross-section. It is noted that the technological realization of such a generator may be constructionally difficult, although the production of a self-sustaining controlled chain reaction is possible in principle.
